

The Importance of Proteins, Minerals, and Vitamins

PROPER animal nutrition is key to successful livestock production. Good nutrition can increase feed efficiency and the rate of gain in animals. Animals must be fed diets that meet their needs. If their needs are not properly met, the animals won't grow, reproduce, or produce milk, and they could possibly die.

Objective:

Describe the importance of proteins, minerals, and vitamins as essential nutrients in animal production.

Key Terms:

amino acids

essential nutrients

fat-soluble vitamins

grass tetany

hemoglobin

inorganic

macrominerals

microminerals

minerals

proteins

vitamins

water-soluble vitamins

white muscle disease

Essential Nutrients in Animal Production

Nutrients required for proper growth in all animals are called **essential nutrients**. There are six classes of essential nutrients—water, carbohydrates, fats, proteins, minerals, and vitamins. The E-unit will discuss the last three of these.

PROTEINS

Proteins are organic compounds that contain carbon, hydrogen, oxygen, and nitrogen and sometimes iron, phosphorus, and sulfur. They are needed to grow new tissues and to repair old tissues in an animal. Every day, 3 to 5 percent of the body's proteins are rebuilt. The highest amounts of proteins can be found in the muscles of animals.

The most common nutrient deficiency is that of proteins. Since most feedstuffs are low in proteins, protein supplements may be necessary. Sources of proteins include soybean meal, cottonseed meal, fish meal, and legume hay. Symptoms of a protein deficiency include anorexia, slow growth rate, decreased feed efficiency, low birth weight, and lower milk production. Proteins are important for weight gain, growth, and gestation. Young animals need diets higher in proteins than older animals. Animals in gestation or lactation stages also need higher levels of proteins in their diets.

Proteins are made up of various combinations of up to 26 amino acids. **Amino acids** are the building blocks of proteins. Amino acids are classified as either essential or nonessential.

Most animals can synthesize the nonessential amino acids. However, the essential amino acids must be supplied in the diets of nonruminant animals. Monogastric animals are unable to synthesize amino acids and thus should have their diets supplemented with proteins containing the 10 essential amino acids. The essential amino acids are arginine, histidine, isoleucine, leucine, lysine, methionine, phenylalanine, threonine, tryptophan, and valine. Ruminants are capable of synthesizing all amino acids by microbial action in the rumen.

MINERALS

Minerals are inorganic elements found in small amounts in the body. **Inorganic** means that the substance does not contain carbon.

To prevent mineral deficiencies, minerals are included in livestock feed rations and are provided through free access to mineral and salt blocks. Mineral deficiencies can result in poor weight gain, poor feed efficiency, and poor reproductive traits.

Minerals are classified as macrominerals or microminerals.

Macrominerals

Macrominerals are minerals needed in the diet in relatively large amounts. Requirements can range from a few tenths of a gram

FIGURE 1. Mineral blocks are provided for grazing animals to lick so the necessary minerals can be obtained.

to one or more grams per day. Macrominerals include calcium, chlorine, magnesium, phosphorus, potassium, sodium, and sulfur.

Calcium and phosphorus are needed in a certain ratio for bone growth and repair and for other body functions. Magnesium is needed for chemical reactions in muscles and for skeletal growth. **Grass tetany**, a potentially deadly condition that occurs in lactating cows on spring pastures, is a result of magnesium deficiency. Potassium aids in the uptake of glucose. Sodium and chlorine are provided by salt (NaCl) and are necessary to maintain water balance and to provide sources of iodine. Sulfur is required for protein synthesis.

Microminerals

Microminerals, or trace minerals, are minerals required in small quantities. These minerals are just as important as macrominerals; they are just needed in smaller amounts. Requirements can range from a millionth of a gram to a thousandth of a gram per day.

Microminerals include chromium, cobalt, copper, fluorine, iodine, iron, manganese, molybdenum, selenium, and zinc. Chromium activates certain enzymes involved in the production of energy. Cobalt is a part of the molecule of vitamin B₁₂. Copper is necessary for normal iron absorption. Fluorine promotes sound bones and teeth. Iodine is needed by the thyroid gland in the synthesis of the hormone thyroxine. Iron is required for the production of hemoglobin. **Hemoglobin** is a protein in the red blood cells that transports oxygen to tissues and carbon dioxide from tissues. Manganese plays an important part in the formation of bone and in blood clotting. Molybdenum serves many purposes and is part of tooth enamel. Selenium, along with vitamin E, helps to prevent white muscle disease. **White muscle disease** is a potentially deadly condition in young calves that is a result of a selenium deficiency. Zinc, in proper amounts, has a major effect on bones, skin, hair, and feathers.

VITAMINS

Vitamins are organic nutrients needed in small quantities to perform specific functions. They do not provide energy but are necessary in the use of energy. Vitamins aid an animal by helping regulate body functions, keeping the body healthy, and promoting resistance to diseases. The deficiency of a vitamin can lead to disease or death. Vitamins are classified as fat soluble and water soluble.

Fat-Soluble Vitamins

Fat-soluble vitamins are vitamins stored in the fat and released as they are needed by the body. Fat-soluble vitamins can be stored for extended periods. They include vitamins A, D, E, and K.

Vitamin A helps maintain internal and external linings and is necessary for a healthy reproductive tract. Vitamin A is not readily available in most feeds. A lack of Vitamin A affects the eyes. Carotene is a precursor of vitamin A. Carotene is found in plants; the body transforms it into vitamin A. The amount of vitamin A in a roughage is typically indicated by the degree of

greenness. Vitamin A deficiency is the most common deficiency in cattle. Signs of a vitamin A deficiency include watery eyes, a rough hair coat, and a reduced growth rate.

Vitamin D regulates the absorption of calcium and phosphorus. Animals make their own vitamin D when exposed to sunlight.

Vitamin E promotes good health. A lack of vitamin E causes failure in the reproductive system. Alfalfa is a good source of vitamin E.

Vitamin K is important in blood clotting. Vitamin K is typically not necessary in the diet, as bacteria in the digestive system produce it.

Water-Soluble Vitamins

Water-soluble vitamins are vitamins dissolved by water. As water passes through the body, it carries out water-soluble vitamins. Thus, these vitamins need to be consumed every day by monogastric animals. Water-soluble vitamins are made by microorganisms in the rumen of a ruminant animal and by fermentation in the cecum of the horse. Water-soluble vitamins include Vitamin C and the B vitamins.

Vitamin C is synthesized in animal tissues. Therefore, it is not necessary to add it to feed rations.

B vitamins are classified into two groups. Group I B vitamins include thiamin, riboflavin, niacin, and pantothenic acid. Group I B vitamins are involved in the release of energy from feed nutrients. Group II B vitamins include folic acid and vitamin B₁₂. Group II B vitamins control the formation of red blood cells.

Summary:

There are six classes of essential nutrients—water, carbohydrates, fats, proteins, minerals, and vitamins. Proteins, minerals, and vitamins were discussed in this E-unit. An animal needs proteins to grow new tissue and repair old tissue. Protein deficiency is the most common nutrient deficiency. Thus, proteins are typically supplemented in the diet. Sources of proteins include soybean meal and legume hay. A mineral is an inorganic element found in small amounts in the body. Minerals can be classified as macrominerals or microminerals. Vitamins are organic nutrients needed in small quantities to perform specific functions. Vitamins are classified as fat soluble or water soluble.

Checking Your Knowledge:

1. Name the six classes of essential nutrients.
2. Describe the function of proteins.
3. Name two sources of proteins.
4. List two symptoms of protein deficiency.

- List the 10 essential amino acids.
- Name the seven macrominerals.
- Describe the function of calcium and phosphorus.
- What is the typical source of sodium and chlorine?
- Name the 10 microminerals.
- Name three symptoms of a mineral deficiency.
- Name the four fat-soluble vitamins.
- What is the function of vitamin D?

Expanding Your Knowledge:

Analyze the nutritional information on a bag of livestock or pet food. What are the major ingredients? What is the percent protein? Which minerals does the food contain, and how much of each mineral is present? Which vitamins does the food contain, and how much of each vitamin is present?
